1. Principal Component Analysis -

a. Apply PCA on CC dataset.

Firstly imported python libraries to do data analysis . Then using read_csv method imported the CC dataset from desktop . And using head() method imported rows of dataset .

```
from sklearn.decomposition import PCA
from sklearn.preprocessing import StandardScaler
from sklearn.model_selection import train_test_split
import pandas as pd
from sklearn.metrics import accuracy_score
import matplotlib.pyplot as plt
import warnings
warnings.filterwarnings('ignore')
```

```
# reading cc dataset
df= pd.read_csv("C:\\Users\\dhara\\OneDrive\\Desktop\\CC GENERAL.csv")
# results top most rows in a data set
df.head()
```

	CUST_ID	BALANCE	BALANCE_FREQUENCY	PURCHASES	ONEOFF_PURCHASES	INSTALLMENTS_PURCHASES
0	C10001	40.900749	0.818182	95.40	0.00	95.4
1	C10002	3202.467416	0.909091	0.00	0.00	0.0
2	C10003	2495.148862	1.000000	773.17	773.17	0.0
3	C10004	1666.670542	0.636364	1499.00	1499.00	0.0
4	C10005	817.714335	1.000000	16.00	16.00	0.0

```
df.shape
```

(8950, 18)

```
#checking any null values are present
df.isnull().sum()
```

```
CUST_ID                               0
BALANCE                               0
BALANCE_FREQUENCY                     0
PURCHASES                             0
ONEOFF_PURCHASES                      0
INSTALLMENTS_PURCHASES                0
CASH_ADVANCE                          0
PURCHASES_FREQUENCY                   0
ONEOFF_PURCHASES_FREQUENCY            0
PURCHASES_INSTALLMENTS_FREQUENCY      0
CASH_ADVANCE_FREQUENCY                0
CASH_ADVANCE_TRX                      0
PURCHASES_TRX                         0
CREDIT_LIMIT                          1
PAYMENTS                              0
MINIMUM_PAYMENTS                    313
PRC_FULL_PAYMENT                      0
TENURE                                0
dtype: int64
```

```
mean1=df['CREDIT_LIMIT'].mean()
mean2=df['MINIMUM_PAYMENTS'].mean()
df['CREDIT_LIMIT'].fillna(value=mean1, inplace=True)   # replacing null values with mean of a colum
df['MINIMUM_PAYMENTS'].fillna(value=mean2, inplace=True)
```

Isnull() is a method of pandas library checks for any values present in data set , In this data set there are a few null values present in minimum payments and credit limit columns. So, these null values are replaced with their column mean value using fillna() method.

To perform PCA on this data set we don't need the output labels because PCA does not rely on the output labels. Using the drop method, we removed a few columns which are unnecessary.

```
# preprocessing the data by removing the columns
X = df.drop(['TENURE','CUST_ID'],axis=1).values
y = df['TENURE'].values
```

From sklearn python library we imported PCA method to perform PCA on the data set. PCA results in a data frame with features having maximum variance with other features by ignoring the duplicate features. Here we reduced the dimensionality of data into two components by keeping k value is equal to 2.

```
# performing PCA
pca2 = PCA(n_components=2)
principalComponents = pca2.fit_transform(X)   # pca is applied on the data set without output label
# creating a data frame for the pca results
principalDf = pd.DataFrame(data = principalComponents, columns = ['principal component 1', 'princip
# adding a new column to the data frame
finalDf = pd.concat([principalDf, df[['TENURE']]], axis = 1)
finalDf   # printing the results
```

	principal component 1	principal component 2	TENURE
0	-4326.383979	921.566882	12

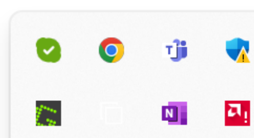
8949	-3623.702535	1555.134786	6

8950 rows × 3 columns



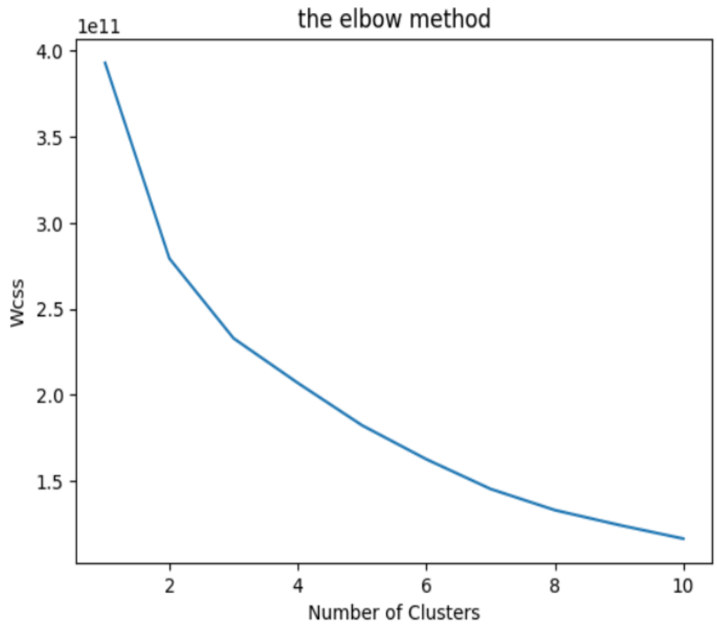
b. Apply k-means algorithm on the PCA result and report your observation if the silhouette score has improved or not?

The elbow method results in a graph from where we need to find the number of clusters value i.e., k value. This method is used to perform k – means algorithm on a dataset . so first need to find the number of clusters required to fit our data together into clusters by using elbow method.

```
# Use the elbow method to find a good number of clusters with the K-Means algorithm

from sklearn.cluster import KMeans
wcss = []
for i in range(1,11):
    kmeans = KMeans(n_clusters=i,init='k-means++',max_iter=300,n_init=10,random_state=0)
    kmeans.fit(X)
    wcss.append(kmeans.inertia_)

plt.plot(range(1,11),wcss)
plt.title('the elbow method')
plt.xlabel('Number of Clusters')
plt.ylabel('Wcss')
plt.show()
```



From graph, the next point to point where the wcss value starts decreasing linearly will be the k value. From the graph below, from number of clusters is 2 the wcss value starts decreasing linearly. So, the number of clusters required to fit our data is 3 i.e., k value is 3. In k-means algorithm k is the number of clusters. So elbow method results in a graph.

The silhouette score has been improved when we perform PCA on the data set. when we applied kmeans on the data set without performing PCA we got a silhouette score of 46.5%. After performing PCA we got a silhouette score of 57%. The silhouette score has been improved by more than 10%.

```python
#  Calculate the silhouette score for the above clustering
# this is the k in kmeans
nclusters = 3
km = KMeans(n_clusters=nclusters)
km.fit(finalDf)
# fitting out kmeans model with our data set
y_cluster_kmeans = km.predict(finalDf)
from sklearn import metrics
score = metrics.silhouette_score(finalDf, y_cluster_kmeans)
print(score)
```

```
0.5720154034623179
```

c. Perform Scaling+PCA+K-Means and report performance.

Using StandardScalar method we performed feature scaling on the data set. Feature scaling is used to normalize the range of all features. We are performing PCA on the feature scaled data set using the PCA method.

```python
# feature scaling using standard scaler
scaler = StandardScaler()
X_Scale = scaler.fit_transform(X)
```

```python
# performing pca
pca3 = PCA(n_components=2)
principalComponents1 = pca3.fit_transform(X_Scale)

principalDf1 = pd.DataFrame(data = principalComponents1, columns = ['principal component 1', 'principal component 2'])

finalDf2 = pd.concat([principalDf1, df[['TENURE']]], axis = 1)
finalDf2
```

7]:

	principal component 1	principal component 2	TENURE
0	-1.718892	-1.072937	12
1	-1.169302	2.509339	12
2	0.938414	-0.382603	12

8947	-0.593879	-1.828113	6
8948	-2.007672	-0.673767	6
8949	-0.217934	-0.418491	6

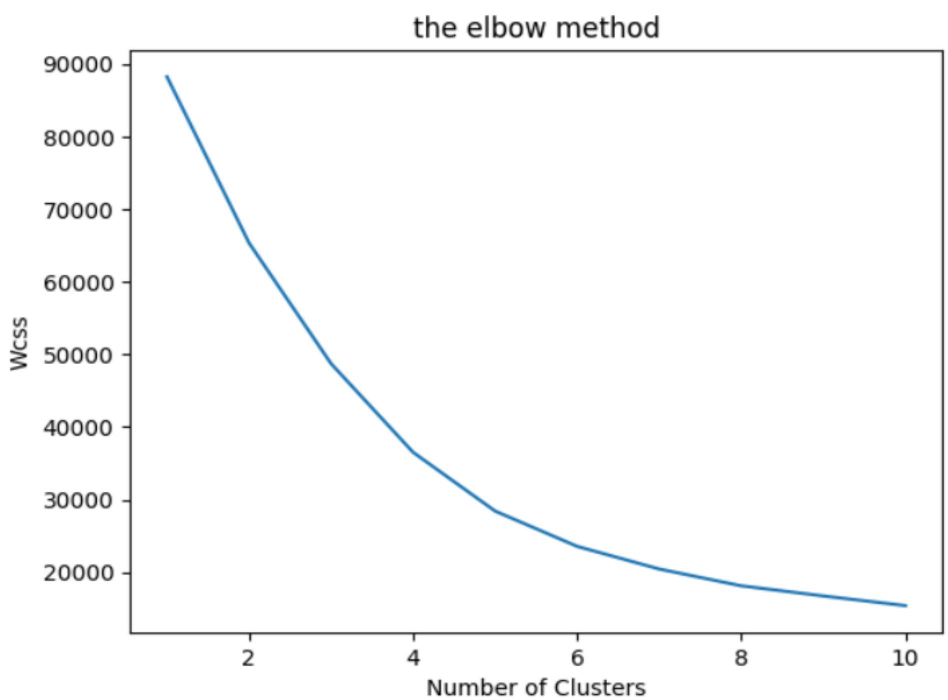
8950 rows × 3 columns

To perform k-means algorithm on a data set first we need to find the number of clusters required to fit our data together into clusters by using elbow methodFrom graph, the next point to point where the wcss value starts decreasing linearly will be the k value. From the graph below, from number of clusters is 2 the wcss value starts decreasing linearly. So, the number of clusters required to fit our data is 3 i.e., k value is 3.

```
# Use the elbow method to find a good number of clusters with the K-Means algorithm

from sklearn.cluster import KMeans
wcss = []
for i in range(1,11):
    kmeans = KMeans(n_clusters=i,init='k-means++',max_iter=300,n_init=10,random_state=0)
    kmeans.fit(finalDf2)
    wcss.append(kmeans.inertia_)

plt.plot(range(1,11),wcss)
plt.title('the elbow method')
plt.xlabel('Number of Clusters')
plt.ylabel('Wcss')
plt.show()
```



Using KMeans method of sklearn library, I applied K- Means algorithm by taking k value as 3 on data set, we got after performing feature scaling and PCA. After performing k-means on this data we got a silhouette score of 38%.

```
#  Calculate the silhouette score for the above clustering
# this is the k in kmeans
nclusters = 3
km = KMeans(n_clusters=nclusters)
km.fit(finalDf2)

y_cluster_kmeans = km.predict(finalDf2)
from sklearn import metrics
score = metrics.silhouette_score(finalDf2, y_cluster_kmeans)
print(score)
```

```
0.38360287729821224
```

2. Use pd_speech_features.csv –

To import a csv file used read_csv method . The head() method is used to get results of rows in a dataset .

a. Perform Scaling – Using StandardScalar method we performed feature scaling on the data set. Feature scaling is used to normalize the range of all features.

b. b. Apply PCA (k=3) - To perform PCA on this data set we don't need the output labels because PCA does not rely on the output labels.

```
df1= pd.read_csv("C:\\Users\\dhara\\OneDrive\\Desktop\\pd_speech_features.csv")     # reading pd_spe
df1.head()
```

	id	gender	PPE	DFA	RPDE	numPulses	numPeriodsPulses	meanPeriodPulses	stdDevPeriodPulses	locPctJitt
0	0	1	0.85247	0.71826	0.57227	240	239	0.008064	0.000087	0.002
1	0	1	0.76686	0.69481	0.53966	234	233	0.008258	0.000073	0.001
2	0	1	0.85083	0.67604	0.58982	232	231	0.008340	0.000060	0.001
3	1	0	0.41121	0.79672	0.59257	178	177	0.010858	0.000183	0.004
4	1	0	0.32790	0.79782	0.53028	236	235	0.008162	0.002669	0.005

5 rows × 755 columns

```
# preprocessing the data
X = df1.drop('class',axis=1).values
y = df1['class'].values
```

```
 #performing feature selection
    scaler = StandardScaler()
X_Scale = scaler.fit_transform(X)
```

To run PCA on the data set, we imported the PCA method from the Sklearn Python package. By discarding the duplicate features, PCA produces a data frame with features that have the greatest variation with other characteristics. Here, we kept the k value at 3, which reduced the data's dimension to three components.

```
# performing pca
pca4 = PCA(n_components=3)
principalComponents2 = pca4.fit_transform(X_Scale)

principalDf2 = pd.DataFrame(data = principalComponents2, columns = ['principal component 1', 'princ
                                                                    'principal components 3'])
finalDf3 = pd.concat([principalDf2, df1[['class']]], axis = 1)
finalDf3
```

c. **Use SVM to report performance –** sklearn module contains train_test_split method to split our data set into training and testing data sets. In this method, test_size defines how much proportion of data to be in the test data set. When we change test_size value whole analysis results will change. Support vector machine algorithm is applied to the data set we got after performing PCA using sklearn module. We got an accuracy of 74.8% when we trained SVM on our data set.

```python
# splitting our data into training and testing part
X_train, X_test, y_train, y_true = train_test_split(finalDf3[::-1], finalDf3['class'], test_size = 0.30, random_state = 0)
```

```python
# training and predcting svm model on our data set
from sklearn.metrics import confusion_matrix
from sklearn.metrics import classification_report
# Support Vector Machine's
from sklearn.svm import SVC

classifier = SVC()
classifier.fit(X_train, y_train)

y_pred = classifier.predict(X_test)

# Summary of the predictions made by the classifier
print(classification_report(y_true, y_pred))
print(confusion_matrix(y_true, y_pred))
# Accuracy score
from sklearn.metrics import accuracy_score
print('accuracy is',accuracy_score(y_pred,y_true))
```

```
              precision    recall  f1-score   support

           0       0.00      0.00      0.00        57
           1       0.75      1.00      0.86       170

    accuracy                           0.75       227
   macro avg       0.37      0.50      0.43       227
weighted avg       0.56      0.75      0.64       227

[[  0  57]
 [  0 170]]
accuracy is 0.748898678414097
```

3. Apply Linear Discriminant Analysis (LDA) on Iris.csv dataset to reduce dimensionality of data to k =2.

Using read_csv method a csv file is imported and using head() method the top rows of dataset are resulted from the pandas library .

Isnull() method of pandas library checks for any values present in data set. In this iris dataset there are no null values.

To perform LDA on this data set we need the output labels because LDA rely on these output labels to reduce the dimensionality of data based on output classes.

```python
#Apply Linear Discriminant Analysis (LDA) on Iris.csv dataset to reduce dimensionality of data to k
# reading iris csv file
df2= pd.read_csv("C:\\Users\\dhara\\OneDrive\\Desktop\\Iris.csv")
df2.head()
```

	Id	SepalLengthCm	SepalWidthCm	PetalLengthCm	PetalWidthCm	Species
0	1	5.1	3.5	1.4	0.2	Iris-setosa
1	2	4.9	3.0	1.4	0.2	Iris-setosa
2	3	4.7	3.2	1.3	0.2	Iris-setosa
3	4	4.6	3.1	1.5	0.2	Iris-setosa
4	5	5.0	3.6	1.4	0.2	Iris-setosa

```python
df2.isnull().any()   # checking null values
```

```
Id               False
SepalLengthCm    False
SepalWidthCm     False
PetalLengthCm    False
PetalWidthCm     False
Species          False
dtype: bool
```

```python
X = df2.iloc[:, 1:5].values    # preprocessing the data
y = df2.iloc[:, 5].values
```

The LinearDiscriminantAnalysis class of the sklearn.discriminant_analysis library can be used to Perform LDA in Python. By setting n_components value as 2 we will get the results in two linear discriminates. We execute the fit and transform methods to retrieve our results.

```
# performing lda on the data set
from sklearn.discriminant_analysis import LinearDiscriminantAnalysis as LDA
lda = LDA(n_components=2)
LinearDA = lda.fit_transform(X, y)
LinearDf = pd.DataFrame(data = LinearDA, columns = ['LD 1', 'LD 2'])   # converting our results int
finalLda = pd.concat([LinearDf, df2[['Species']]], axis = 1)   # appending species column to the da
finalLda
```

	LD 1	LD 2	Species
0	8.084953	0.328454	Iris-setosa

4. Briefly identify the difference between PCA and LDA –

Dimensionality reduction is a technique in machine learning that involves selecting a subset of important variables to reduce the number of random variables being analyzed. Two main algorithms used in dimensionality reduction are Principal Component Analysis (PCA) and Linear Discriminant Analysis (LDA). PCA is an unsupervised method that identifies the data set's maximum variance between features, disregarding duplicates of other features. Since the variance between the features is unrelated to the outcome, PCA does not depend on output labels. On the other hand, LDA is a supervised method that considers output labels to reduce the feature set dimensions and determine a decision boundary. LDA projects data points onto new dimensions so that the clusters are as distinct from one another as possible, and the individual components of a cluster are as near the cluster centroid as possible.
